Astrophysical Observations Dark

Dark matter is a form of matter thought to account for approximately 85% of the matter in the universe and about a quarter of its total mass–energy density or about $2.241 \times 10^{-27} \text{ kg/m}^3$. Its presence is implied in a variety of astrophysical observations, including gravitational effects that cannot be explained by accepted theories of gravity unless more matter is present than can be seen.

Dark matter - Wikipedia

While there is definitely dark matter in the universe—in the form of CDOs and/or in other forms—the most surprising result of my papers of 2020 is the following: It is quite possible that dark matter or a part of it is represented not by some largely

Dark matter haloes can also affect how light bends around astrophysical objects in a process called gravitational lensing. But the signals left in the stellar distributions are weak and prone to confusion with the stars' own motions. Another way to probe the effect of haloes is by looking at the galactic gas it affects.
